How does a voltage level change without an inverter?

In the beginning, the voltage level is within the declared value of 230 V. The inverter feeds a low amount of reactive power (≈ 90 VAR). After 0.3 s, the voltage level drops by 14 V without the inverter. Fig. 8a shows both waveforms of the voltage level changing with both the inverter and without the inverter.

The rapid increase in using PV inverters can be used to regulate the grid voltage and it will reduce the extra cost of installing capacitor banks. Currently, there are multiple ongoing research applications and experiments focusing on this general concept of using a PV inverter as a VAR compensator [3-5].

Voltage Rise Wires have resistance causing Voltage Drop. All grid-tied inverters increase voltage to export power. Typically they only need to raise the voltage above the grid and any wire resistance. Enphase calls this voltage rise, or Vr_{rise}. The total voltage rise shouldn't exceed 2% of the grid voltage, otherwise, it can trip the microinverter.
