Can RBD predict reliability of uninterruptible power supplies (UPS)?

34.4 Conclusion This paper proposed the RBD for the reliability analysis of uninterruptible power supplies (UPS). RBD is found to be a simple and effective method to predict the important reliability parameters of UPS systems. The main advantage of this method is its simplicity in constructing the RBD reliability model compared to other methods.

How are reliability parameters of DC uninterruptible power systems presented?

Conventionally, reliability parameters of the DC uninterruptible power systems are presented by using the state-space method. In this approach, firstly, all the possible system states have to be identified. Then, the state-transition diagram has to be constructed in order to show the interdependencies between the states.

Does sensitivity analysis affect the reliability of DC UPS?

Sensitivity analysis on the major components of the DC UPS is performed to investigate the effect on the overall reliability of the power systems. Field data from industrial best practice are used to validate the results of the analytical model. Keywords Uninterruptible power supply; Reliability block diagram; Mean time between failures

How to determine the reliability and availability of a UPS system?

To determine the reliability and availability of a UPS system, a method based on Monte Carlo simulation was used in [6,7]. Furthermore, techniques, such as fault tree analysis and Bayesian networks, have been employed to document a number of system parameters to determine the probability of system failure.

Does a generator increase the availability of a DC UPS system?

The failure rate of the generator is found to be low enough to affect the overall system failure rates. The unavailability of the system without generator is lower, and this can suggest that inclusion of generator unit in the DC UPS configuration can increase the availability of the overall system.

How does a DC UPS system work?

This is the most basic configuration of the DC UPS system [9]. From the system configuration in Fig. 34.3, it is shown that under the utility failure condition, the back-up time depends solely on the battery system. Once the utility power resumed, the rectifier will feed DC supply to the critical DC loads and charge the battery.

To obtain a uninterruptible power supply- and therefore suitable sized in relation to the load to be protected - it is necessary to clearly identify various aspects.
